

Preface

As its name implies, space science is the study of space, i.e. “Taikong” in Chinese, or more specifically scientific research that has to be carried out in space. To be exact, with spacecraft as the main tools, space science is defined as the study of natural phenomena and their underlying rules in physics, astronomy, chemistry, and life sciences which exist in solar-terrestrial space, interplanetary space, and even the universe as a whole. In October 1957, the first man-made satellite “Sputnik” was launched. Since then, unprecedented new instruments and methods have been developed in order to explore space, and a stream of revolutionary discoveries has been achieved. These discoveries have, in essence, revealed a completely new universe, and profoundly changed our understanding of nature and human beings, as well as human life itself. Einstein predicted that the frontier of natural science would gradually shift to both macro and micro forefronts, and current research in space science is aimed at both the universe in the macroscopic sense, and particles and the origin of life in the microscopic sense. Among them, the search for dark matter and dark energy, detection of gravitational waves, and so on, continues to lead the development of human society, and open up new scientific fron-

tiers.

Being highly explorative, the study of space science constantly demands novel instruments and spacecraft technologies, and the acquisition of new data mainly rests on the progress of new techniques. This trend greatly boosts the development of space technologies, which also extends to applications, bringing about potential economic benefits. Thus, space science has become the main driving force of space technologies and applications. It is also one of the major areas which engenders international cooperation. The first reason to go for international cooperation is because any discoveries need not to be duplicated. It is vital for both the decision makers and scientists to avoid duplication when planning a mission. The second reason is that the number of approved missions are always much less than that of the proposals due to the limited funds. The scientists' demands are unlimited while the government's investment is limited. The need to combine financial resources is becoming more and more pressing because of the increasing size and scope of space programs, and smoothly coordinated programs can often at least double their overall output.

China has launched more than 100 application satellites since 1970 when her first man-made satellite—Dongfanghong-1 was successfully launched. A relatively comprehensive satellite system for various applications has been established, and China has gradually developed into one of the world's space powers. After the lift-off of the "Wukong" mission on December 2015, i.e. DArk Matter Particle Explorer (DAMPE) satellite

whose official delivery to the scientific user was in March 2016, and the launch of SJ-10 in April 2016, the first Chinese microgravity and life sciences mission, further missions will follow. QUantum Experiment at Space Scale (QUESS) and Hard X-ray Modulation Telescope (HXMT) will be launched successively in 2016. Chinese space science is entering its most exciting era. However, the existing space science missions generally follow the principle of a case-by-case approval system, lacking a stable funding system as well as a long-term national program.

In order to advance China's space science, and provide scientific input and suggestions for future development and national budget allocation, the National Space Science Center (NSSC), Chinese Academy of Sciences (CAS) has led a study on future space science programs in China in 2016-2030 supported by the Space Priority Program (SPP) on Space Science of CAS. The report, one of the results of the study, is a short version of the original study report in Chinese. It consists of 7 chapters. The first chapter is the overview. Chapter 2 introduces the status of space science in China. Chapter 3 poses the scientific questions to be addressed by the Chinese space science community in 2016-2030, of which the two themes are: a) How did the universe and life originate, and how do they evolve? b) What's the relationship between the solar system and human beings? Chapter 4 is the core of this report. The strategic goals, space science programs and missions, the roadmap through 2030 and the implementation approaches are proposed hereby in the chapter. Chapter 5 probes into the tech-

nologies required. Chapter 6 provides an outlook of space science beyond the year 2030. Chapter 7 concludes the report.

List of main contributors:

Wu Ji, the study team leader, responsible for the main themes, the coordination of the subtopics, and the final review of the report.

Sun Lilin, Fan Quanlin, Bai Qingjiang and You Liang (NSSC, CAS), responsible for compiling the report.

Zhang Shuangnan, Lu Fangjun (Institute of High Energy Physics, CAS), and Chang Jin [Purple Mountain Observatory (PMO), CAS], responsible for preparing the text in astrophysics.

Gan Weiqun (PMO, CAS) and Yan Yihua [National Astronomical Observatories, CAS (NAOC)], responsible for preparing the text in space solar physics.

Wang Chi and Xu Jiyao (NSSC, CAS), responsible for preparing the text in space physics.

Zou Yongliao (NAOC) and Li Lei (NSSC, CAS), responsible for preparing the text in planetary science.

Shi Jiancheng (Institute of Remote Sensing and Digital Earth, CAS), Hu Xiong (NSSC, CAS) and Chen Hongbin (Institute of Atmospheric Physics, CAS), responsible for preparing the text in space Earth science.

Liu Qiusheng, Kang Qi and Wang Shuangfeng [Institute of Mechanics (IM), CAS], Pan Mingxiang (Institute of Physics, CAS), and Feng Ji (Beijing Advanced Sciences and Innovation Center, CAS), responsible for preparing the text in microgravity science.

Zhang Yuanzhong (Institute of Theoretical Physics, CAS), responsible for preparing the text in space fundamental physics.

Long Mian (IM, CAS) and Liu Zhiheng (Institute of Microbiology, CAS), responsible for preparing the text in space life sciences.

Meng Xin (NSSC, CAS), responsible for preparing the text in space integrated technologies, etc.

After the draft compiled, it has been presented to the National Space Science Committee, and valuable advice has been obtained. It has also been forwarded to a number of recognized international scholars affiliated to the institutes and universities in France, Russia, USA, the Netherlands, Italy, UK, Germany, Finland, Belgium, Canada, Hong Kong China, and Taiwan China to review the report, whose suggestions and comments are very helpful and valuable. Our heartfelt thanks goes to the following scientists, of whom Roger-Maurice Bonnet is the lead reviewer:

Roger-Maurice Bonnet, European Space Agency, France.

Lev Zelenyi, Russian Academy of Sciences (RAS), Russia.

Cui Wei, Department of Physics, Purdue University, USA.

Leonid Gurvits, Joint Institute for VLBI in Europe, the Netherlands.

Marco Feroci, High Energy Astrophysics section, Italian National Institute of Astrophysics, Italy.
